CSCE 314 Reference Sheet Last Updated: May 1, 2017© Josh Wright 2017

General:

- `newtype Parser a = P (String -> [(a,String)])`
- Predicate: a function that takes one argument and returns a boolean
  - if `pred x == True` then `x` satisfies predicate `pred`
- function composition:

```
-- the . operator composes functions:
(f . g) x == f (g x)
```

useful library functions:

```
-- Data.List
nubBy :: (a -> a -> Bool) -> [a] -> [a]
nubBy pred xs = -- unique elements only from xs as
                -- determined by pred
nub :: Eq a => [a] -> [a]
nub xs = nubBy (==) a -- unique elements from xs
--
words :: String -> [String]
words xs =  -- list of whitespace-separated
            -- words from xs
--
-- concatenate container of lists
concat :: Foldable t => t [a] -> [a]
-- or for list-of-lists specifically:
concat :: [[a]] -> [a]
concat xs = foldl (++) [] xs
--
-- like concat, but use a function to get the inner lists
concatMap :: (a -> [b]) -> [a] -> [b]
concatMap f xs =  foldr ((++) . f) [] xs
--
-- get the longest prefix of xs for which pred is true and
↪  also return the rest of the list
span :: (a -> Bool) -> [a] -> ([a], [a])
span pred xs = (takeWhile pred xs, dropWhile pred xs)
--
-- repeat a = infinite list of a
repeat :: a -> [a]
repeat x = map (\_ -> x) [1..]
repeat x = [ x | _ <- [1..] ]
-- replicate n a = list of length n repeating a
replicate :: Int -> a -> [a]
replicate n x = map (\_ -> x) [1..n]
replicate n x = [ x | _ <- [1..n] ]
--
-- folds (works on any foldable, not just lists)
foldr :: (a -> b -> b) -> b -> [a] -> b
foldr f z [a,b,c] = a `f` (b `f` (c `f` z))
foldr f z [a,b,c] = f a $ f b $ f c z
-- combines into z from right to left
-- can potentially work on an empty list if one of the folds
↪  does not evaluate it's second argument
foldl :: (b -> a -> b) -> b -> [a] -> b
foldl f z [a,b,c] = ((z `f` a) `f` b) `f` c
foldl f z [a,b,c] = f (f (f z a) b) c
-- evaluates from right to left
-- will not work on infinite list because it must start at the
↪  end of the list
--
-- these are the same as above, except they take the first two
↪  elements for the first application of f
foldr1 :: (a -> a -> a) -> [a] -> a
foldl1 :: (a -> a -> a) -> [a] -> a
```

Parsing.hs:

- `sat :: (Char -> Bool) -> Parser Char`
  - returns a character if that character satisfies the predicate
- `digit, letter, alphanum :: Parser Char`
  - parses a digit, letter, or alpha-numeric letter respectively
- `char :: Char -> Parser Char`
  - `char 'a'` parses exactly the character `'a'`
- `item :: Parser Char`
  - parses any character
- similar to above: `digit letter alphanum lower upper string`
- `many :: Parser a -> Parser [a]`
  - parses 0 or more instances of `a` and collects them into a list
- `many1 :: Parser a -> Parser [a]`
  - same as `many`, but
- `(+++)` choice:
  - parse first argument if possible, else parse second argument
  - first successfully parsed argument is returned

```
(+++) :: Parser a -> Parser a -> Parser a
p +++ q =  P (\inp -> case parse p inp of
                   []        -> parse q inp
                   [(v,out)] -> [(v,out)])
```

- `((>>=))` sequential composition
  - `a >>= b` unboxes monad `a` into an output `a0` and then unboxes monad `b` with input `a0`

```
type Parser a = String -> [(a, String)]
-- implementation for in-class mostly-complete parser
↪  'monads'
(>>=) :: Parser a -> (a -> Parser b) -> Parser b
(>>=) p1 p2 = \inp -> case parse p1 inp of
       []  ->  []
       [(v, out)] -> parse (p2 v) out
```

  - usage:

```
doubleDigit :: Parser [Char]
doubleDigit =
  digit >>= \a ->
  digit >>= \b ->
  return [a,b]
-- is equivalent to
doubleDigit' :: Parser [Char]
doubleDigit' = do
  a <- digit
  b <- digit
  return [a,b]
```

  - `(>>)` is the same except that it discards the result of the first monad (thus it has signature `(>>) :: Parser a -> Parser b -> Parser b`)

Parsing Examples:

- bind and lambda method of parsing:
  - parse a number:
- parse arithmetic expressions using do syntax:

```
expr :: Parser Int
expr  = do t <- term
           do {char '+'
              ;e <- expr
              ;return (t + e)
              }
             +++ return t
term :: Parser Int
term  = do f <- factor
           do char '*'
              t <- term
              return (f * t)
            +++ return f
factor :: Parser Int
factor  = do d <- digit
             return (digitToInt d)
           +++ do char '('
                  e <- expr
                  char ')'
                  return e
eval   :: String -> Int
eval xs = fst (head (parse expr xs))
```

Trees:

- represent either a leaf node or some kind of internal node
- arithmetic tree declaration:

```
data Expr = Val Int
          | Neg Expr
          | Add Expr Expr
          | Mul Expr Expr
```

- how to fold over a tree:

```
-- exprFold  valF        negF      addF
exprFold :: (Int->b) -> (b->b) -> (b->b->b) ->
-- mulF        input   output
  (b->b->b) -> Expr -> b
exprFold valF _ _ _ (Val i) = valF i
exprFold valF negF addF mulF (Neg e)
  = negF  (exprFold valF negF addF mulF e)
exprFold valF negF addF mulF (Add s1 s2)
  = addF  (exprFold valF negF addF mulF s1)
          (exprFold valF negF addF mulF s2)
exprFold valF negF addF mulF (Mul s1 s2)
  = mulF  (exprFold valF negF addF mulF s1)
          (exprFold valF negF addF mulF s2)
```

  - basically, just collect values into some type `b` and use supplied functions at each node to fold into single value
  - useful for evaluating simple things like:

```
-- evaluate an expression
evalExpr'    = exprFold id (\x -> 0 - x) (+) (*)
id --  integers map to integers
(\x -> 0 - x) -- negation
-- everything else is just simple numeric operators
--
-- count leaves in a tree
countLeaves' = exprFold (\_ -> 1) id (+) (+)
(\_ -> 1) -- leaf integer node is one node
id -- negation node has only one child, pass on count
(+) (+) -- nodes with two children: add number of leaf
↪  grandchildren
```

HW2: Water Gates:

```
waterGate :: Int -> Int
waterGate n =
 length -- number of True's
 $ filter id -- filter just True's
 $ waterGate' n initial -- initial call to helper
```

```haskell
  where
    -- start with all gates closed
    initial = replicate n False
    --
    -- flip states
    waterGate' 1 state = map not state
      -- base case: flip every state
    waterGate' n state = flip n $ waterGate' (n-1) state
    -- otherwise, first get the state for (n-1) and then flip
↪   every nth state
    --
    -- flip every nth gate
    flip :: Int -> [Bool] -> [Bool]
    flip 1 xs = map not xs -- flip every gate
    -- flip only gates which index are multiples of n
    flip nth xs = [ if (i `mod` nth == 0) then not x else x
                  -- zip each state with it's index
                  | (x,i) <- (zip xs [1..])  ]
```

HW2: Goldbach's Other Conjecture:

```haskell
-- check if a number is prime
primeTest :: Integer -> Bool
primeTest 1 = False
primeTest t =  and [ (gcd t i) == 1 | i <- [2..t-1]]
-- all numbers less than n that are double a square
twiceSquares :: Integer -> [Integer]
twiceSquares n = takeWhile (<n) [ 2 *x^2 | x <- [1..]]
-- list of odd numbers
oddList = map (\x -> 2*x + 1) [0..]
-- all odd numbers that are composite (not prime)
allOddComp = [ o | o <- (drop 1 oddList)
                 , not (primeTest o)     ]
-- if a number satisfies conditions for conjecture
-- method: for enough square nubmers, check if n-(that number)
↪   is prime
satsConds n = or [ primeTest k |
                   k <- map (\x->(n-x)) (twiceSquares n) ]
-- find the first number
goldbachNum = head [ x | x <- allOddComp
                       , not (satsConds x) ]
```

HW4: Sets:

```haskell
type Set a = [a]
a = mkSet [1,2,3,4,5]
b = mkSet [1,2,3]
addToSet :: Eq a => Set a -> a -> Set a
addToSet s a | a `elem` s = s
             | otherwise = a : s
mkSet :: Eq a => [a] -> Set a
mkSet lst = foldl addToSet [] lst
isInSet :: Eq a => Set a -> a -> Bool
isInSet [] _ = False
isInSet [a] b = a == b
isInSet (x:xs) b | x == b = True
                 | otherwise = isInSet xs b
subset :: Eq a => Set a -> Set a -> Bool
subset sub super = and [ isInSet super x | x <- sub  ]
setEqual :: Eq a => Set a -> Set a -> Bool
setEqual a b = subset a b && subset b a
-- instance (Eq a) => Eq (Set a) where
--   a == b = subset a b && subset b a
setProd :: Set a -> Set a -> [(a,a)]
setProd a b = [ (ai,bj) | ai <- a
                        , bj <- b
                        ]
```

Prev Exam: Run Length Encoding:

```haskell
import Parsing
import Data.Char
q4 = do
  d <- sat isUpper
  e <- char (toLower d)
  f <- many item
  return [d,e]
ones = (map (\_ -> 1) [1..])
myRLE [] = []
myRLE ls = myhelper (zip ones ls)
myhelper [(n,c)] =  [(n,c)]
myhelper ((n,c):(m,d):rest)
  | (d == c)  = myhelper (((n+m),c):rest)
  | otherwise = (n,c):myhelper ((m,d):rest)
```

Rock Paper Scissors:

```haskell
data RPS = Rock | Paper | Scissors
  deriving (Eq, Show)
rps :: RPS -> RPS -> Int
rps a b | a == b = 0
rps Rock     Scissors = 1
rps Paper    Rock     = 1
rps Scissors Paper    = 1
rps _        _        = 2
rps2 :: RPS -> RPS -> Int
rps2 a b =
  if a == b then 0 else case (a,b) of
    (Rock,     Scissors) -> 1
    (Paper,    Rock)     -> 1
    (Scissors, Paper)    -> 1
    _ -> 2
```

99 problems:

```haskell
-- 9. pack consecutive duplicates into sublists
pack (x:xs) = let (first,rest) = span (==x) xs
              in (x:first) : pack rest
pack [] = []
-- example:
pack [1,2,3,2,2,3] == [[1,1],[2],[3],[2,2],[3]]
```

Java:

Inheritance and Virtual Methods:

- TODO

Generics:

- TODO

```java
import java.lang.*;
class GenericWildcards {
  // T is the binding of the generic parameter
  private static class GenericBox<T> {
    // it is optional, but we need it if we want to do things
↪    with that type
    public T t;
    public GenericBox(T t) { this.t = t; }
  }
  private static class NumberBox<T extends Number> {
    public T t;
    public NumberBox(T t) { this.t = t; }
  }
  public static void printBox(GenericBox<?> b) {
    // here we use the ? wildcard with no type binding because
↪    we don't need to do things with that type specifically
    System.out.println(b.t);
  }
  // method generic goes before return type
  public static <T> void printWithParameter(GenericBox<T> b) {
    System.out.println(b.t);
  }
  public static void main(String[] args) {
    // this is using raw types, generally considered bad
    GenericBox rawBox = new GenericBox("asdf1"); // compiler
↪    warnings
    // this cast is ok because raw types hold
↪    java.lang.Object
    Object o1 = rawBox.t;
    // this causes no warnings for same reason as assignment
↪    above doesn't
    printBox(rawBox);
    // this is just using an unknown type, java says it's
↪    fine
    GenericBox<?> unknownBox = new GenericBox<>("asdf2");
    // this is also OK because <?> explicitly makes the
↪    generic parameter as java.lang.Object
    Object o2 = unknownBox.t;
    printBox(unknownBox);
    GenericBox<String> stringBox = new GenericBox<>("asdf3");
    // the type parameter above allows Java to infer that this
↪    cast is safe
    String s = stringBox.t;
    System.out.println(s);
    // must specify type between class access and method name
↪    (works the same for instance methods too)
    GenericWildcards.<String>printWithParameter(stringBox);
    ////////////////////
    // correct stuff works like expected
    NumberBox<Integer> nb1 = new NumberBox<>(5);
    System.out.println(nb1.t + 1);
    //
    // this will fail to even allow NumberBox<String> because
↪    that type doesn't work
    // NumberBox<String> sb1 = new NumberBox<>("asdf");
    //
    // this will fail because the inferred type of
    NumberBox<>("asdf") is NumberBox<String>, which isn't
↪    allowed
    // NumberBox<?> sb1 = new NumberBox<>("asdf");
  }
}
```

Locks: `ReentrantLock` and `Condition`:

```java
import java.util.concurrent.locks.ReentrantLock;
```

- `ReentrantLock`: basically a mutex
- `ReentrantLock.lock()`: acquire the lock (blocking)
  - does **not** throw `InterruptedException`
- `ReentrantLock.unlock()`: release the lock
  - does **not** throw `InterruptedException`

* you should always wrap your locking code in a `try{}` block (including the call to `lock()` itself) and put the call to `unlock()` in a `finally{}` block.
  This way, `unlock()` gets called no matter any exception

```
import java.util.concurrent.locks.Condition;
```

- created from a lock, allows one thread to send a message to another thread
  * create form lock instance using `lock.newCondition()`
- `await()`: release this lock and wait for the condition to be signaled.
  When the signal happens, `await()` will automatically re-acquire the lock before returning
  (this means you will still have to unlock manually)
  * you can only `await()` when you are holding the lock, and when it returns, you still have the lock, so it acts like you never unlocked it
  * **does** throw `InterruptedException`
- `signal()`: wake up a single thread that is waiting on the condition

  * must be holding lock to signal it's condition
  * must manually release lock before other thread will return from `await()` (because the other thread must also acquire the lock)
  * does **not** throw `InterruptedException`
- `signalAll()`: similar to `signal()` except that every thread is woken up
  * still only one thread will be able to use the lock-protected resource at a time, because locks
  * does **not** throw `InterruptedException`

```
import java.lang.*;
import java.util.concurrent.locks.ReentrantLock;
import java.util.concurrent.locks.Condition;
public class Main2 {
  public static class Counter {
    public int count = 0;
    public ReentrantLock lock;
    public Condition updated;
    public Counter() {
      this.lock = new ReentrantLock();
      this.updated = lock.newCondition();
    }
  }
  public static class CounterThread implements Runnable {
    private Counter counter;
    public CounterThread(Counter c) {counter = c;}
    @Override
    public void run() {
      while (true) {
        try {
          counter.lock.lock();
          counter.count += 1;
          System.out.println(counter.count);
          counter.updated.signalAll();
        }
        // lock() does not throw InterruptedException
        // catch (InterruptedException e) {}
        finally {counter.lock.unlock();}
        try {
          Thread.sleep(1000);
        } catch (InterruptedException e) {}
      }
    }
  }
  public static class IntervalPrinter implements Runnable {
    private Counter counter;
    private int mod;
    private String message;
    public IntervalPrinter(Counter c, int mod, String msg) {
      counter = c;
      this.mod = mod;
      message = msg;
    }
    @Override
    public void run() {
      while (true) {
        int val = 0;
        try {
          counter.lock.lock();
          counter.updated.await();
          val = counter.count;
        }
        catch (InterruptedException e) {}
        finally {counter.lock.unlock();}
        if (val % mod == 0) {
          System.out.println(message);
        }
      }
    }
  }
  public static void main(String []args) {
    Counter c = new Counter();
    new Thread(new IntervalPrinter(c,3,"fizz")).start();
    new Thread(new IntervalPrinter(c,5,"buzz")).start();
    new Thread(new CounterThread(c)).start();
  }
}
```

Reflection:

`java.lang.Class<T>`:
- allows you to reflect on class `T`
- `toString()` returns class declaration (more or less)
- `getSimpleName()` returns just the name part of it
  * `Main.class.getSimpleName()` → `"Main"`
- to get:
  * `Class<?> c = SomeClassName.class;`
  * `Class<?> c = someObjectInstance.getClass();`
  * `Class<?> c = Class.forName("SomeClassName");`
    - throws `ClassNotFoundException`
- `Method[] getMethods()`
  * all public member methods, including those inherited from superclasses and implemented in interfaces
- `Method[] getDeclaredMethods()`
  * excludes inherited methods, includes any that are declared in class regardless of public, private, static, etc...
- `Constructor<T> getConstructor(Class<?>... pt)`
  * get a constructor for `T` that matches parameter types `Class<?>... pt`
  * throws `NoSuchMethodException` if there is no constructor matching those parameter types
- `T newInstance()`
  * create a new instance of `T` using the default constructor
- TODO use `Constructor` class to create class using non-default constructor
- TODO fields

`java.lang.reflect.Method`:
- `String toString()` → method prototype as string
  * includes modifiers, method name, parameters, etc...
- `String getName()` → name of method as string
- `int getModifiers()` → `int` representing modifiers
  * use `java.lang.reflect.Modifier` static methods to check:
    `Modifier.isStatic(m.getModifiers())`
- `Class<?>[] getParameterTypes()` → types of parameters of method
  * if no parameters, returns empty array
  * does not include implicit `this` parameter for instance methods
- `Type[] getGenericParameterTypes()`: same, but returns a `Type` instance that accurately represents the generic info from the actual source
- `Class<?> getReturnType()`: get the return type
  * if it's void, it returns a void type
- `Object invoke(Object obj, Object... args)`
  * invoke a method on an object. Subject to virtual method lookup

  * if the method is static, `obj` may be null
  * if the method returns a primitive type, it is wrapped; if void, returns null
  * throws `IllegalAccessException` if you can't run that method because it's private or something
  * if target method throws, it throws `InvocationTargetException` wrapping whatever was thrown
